Cytochrome c oxidase: putative interactions with the outer mitochondrial membrane. The cytochrome c oxidase complex (CcO) is the terminal enzyme of the aerobic respiratory chain. It catalyzes the reduction of oxygen to water through the transfer of electrons across the inner mitochondrial membrane from cytochrome c to molecular oxygen. The complex consists of 12 subunits organized into an inner membrane subcomplex and a larger peripheral homologous subcomplex, each having a heme-containing metalloprotein at its center. Recently, the crystal structure of CcO has been solved. In addition, the ligands of heme a and of the Cu(B) center have been identified. It is suggested that the peripheral subcomplex binds cytochrome c or cytochrome c1, both of which contain negatively charged residues near the ligand binding site. The acidic residues, aspartate and glutamate residues, are likely to interact with the inner membrane. It is suggested that two of the ligands to the Cu(B) cofactor, the Cu(B)(I) and the Cu(B)(II), are histidine residues and a third lig
