manipulation & exploration, and much more. Frequently asked questions (FAQ)Q: Why would SQL Server 2005/2008 be caching a particular cached plan and not returning the same plan even if the query changes? There is a SELECT statement that runs pretty quickly that has a non-clustered index on it. We have some

---

queries that are more than 20 minutes long and find that they end up using the same cached plan. However, after changing the query, the new query seems to use a new cached plan (as it is being executed). Both queries have the same LIKE 'value%' text in them. The SQL Server is running as SQL Server 2008 R2 Enterprise. Do

---

you know what would cause SQL Server to cache the same plan for this query, even though it is a completely different query? A: As an answer to the original question, does SQL Server know what the query will return (the answer here, from the SQL Server blog, is no): Because SQL Server does not have any knowledge of the order in

---

which the entities in the middle of the query are executed, it cannot use any information it has regarding the positions of the various entities, such as which entity happens to follow which other entity in the query. If an unnamed, contextually dependent subquery happens to be evaluated first, there is no way for SQL Server to know that

---

this unknown subquery happens to have a useful place for an index hint. I guess, in this case, the query is evaluated before it is cached, and thus the cached plan can't be reused. a> Generated on Tue Dec 28 2014 13:35:32 for Repetier-Firmware by
